How does a UPS work? Uninterrupted power supplies protect electronics from power disturbances. Acting as a safeguard, a UPS provides backup power and ensures uninterrupted power supply to connected devices. It typically consists of a battery and an inverter, which converts DC power from the battery into AC power for the load. The UPS also has an input connection to the power grid or an external power source like a generator. In the event of a power outage, the UPS immediately switches to battery power to maintain the load until the primary power source is restored. This ensures that sensitive equipment, such as computers and medical devices, can continue to operate without interruption, protecting data and preventing damage. UPS units are available in various sizes and capacities to suit different needs, from small home units to large industrial systems. They are essential for maintaining the reliability and uptime of critical infrastructure and data centers.
